In these days, when quantum computers are about to be invented, people are just still living in the realm of classical computers which have a huge memory capacity but tiny speed. If we are talking about speed, it doesn't matter how much the memory space is as long as the processor can move fast enough to perform massive number calculations. The problem with classical computers is that they are too slow and very pricey, they don't have enough time to process large amount of data efficiently. Meanwhile, nowadays, quantum computers are coming very close to their realization. These quantum computers that provide a lot more of memory than their classical counterparts are also being built at a cheaper rate. This newly developed quantum computers are capable of performing number calculations a lot faster than any classical computer. The main difference between a classical computer and a quantum computer is that the latter is very small and has a lot less memory. Since classical computers can run at insanely fast speeds, we can't really use them for number crunching. On the other hand, quantum computers can easily run tests in seconds whereas classical computers can take years to complete the same tests. This is why quantum computers are pretty interesting.
